version 1.0 · October 2026

An economy is a web of connections, and decisions are made from numbers

for a connection to become a number, its participants must first be sorted into groups

01 **An economy is a set of connections**
who produced what, sold it to whom, spent it on what, owns what

02 **A decision requires measurement**
a rate, a budget, an investment — all rest on numbers collected into a table

03 **Variety prevents simple addition**
millions of products, jobs and transactions, each unique in its own way

04 **Hence classifications**
an agreement on what counts as the same, so that different things can be added up

A classification does not describe an economy — it decides what counts as the same thing in it.
That is why an argument about a code is almost always an argument about substance.

One plant, two dozen codes

an oil refinery will run through the whole deck, collecting codes as it goes

what is coded	classification	code
activity	OKVED2 ← NACE ← ISIC	19.20
product	OKPD2 ← CPA ← CPC	19.20.21 petrol
exports	TN VED EAEU ← HS	2710
sale to households	COICOP	07.2.2 fuel
budget subsidy	COFOG + KOSGU	04.3 fuel and energy
foreign currency proceeds	BPM7	current account
unit operators	OKZ ← ISCO	3134

None of them is “the company's code”: each answers its own question.
The full passport of the object comes at the end of the deck.

A classification is not a formality but a definition of the subject

until an object is assigned to a group there is nothing to count

- a wrong code puts the indicator in someone else's industry, and so in every table
- different versions — countries measure the same thing but add it up differently
- a change of version breaks the series where the economy did not change
- different systems — output, imports and consumption do not reconcile

A discrepancy in data is almost always first blamed on the method of calculation.
The classification is what should be checked first.

Three questions to ask of any code

these three questions organise the whole deck

01

What is being classified

an activity, a product, a function, a unit or a person

→ the sections “Economic classifications” and “People, units, territories”

02

Which version

each family has its own numbering of generations and its own lifespan

→ the “Versions …” slides in each block and the timeline at the end

03

Who carries out the transposition

an international standard does not apply in a country by itself

→ the “Russia” section and the table of responsible bodies

There are many abbreviations here: all of them are spelled out in the appendix at the end — international ones and Russian ones separately.

I

Families of classifications

activities, products, goods, consumption — one at a time and in full

Three storeys: standard, region, country

countries do not invent schemes anew — they inherit codes and subdivide them further

international		regional		national
ISIC	→	NACE (EU)	→	OKVED2
CPC		CPA (EU)		OKPD2
HS		TN VED (EAEU)		applied by the customs service
COICOP		—		the consumer basket
ISCO		—		OKZ

Not every family has a middle storey: HS reaches Russia through the EAEU, while COICOP is applied directly, with no regional version.

Who writes the standards

each family has its own publisher, and that sets the pace of revisions

organisation	what it publishes	revision cycle
UN Statistical Commission	SNA, ISIC, CPC, COICOP, COFOG	every 15–17 years
IMF	BPM, GFSM, MFSM	together with the SNA
World Customs Organization	HS	every 5 years
Eurostat	NACE, CPA, PRODCOM, ESA	following the UN
ILO	ISCO, ICSE	rarely, every 20 years
UNESCO	ISCED	rarely

Different cycles are a source of mismatch: goods codes change twice in the time it takes to update the activity codes once.

Harmonisation: codes coincide up to a certain digit

this is what determines where data are comparable and where they are not

19.20.21

up to four digits — the international part

deeper — the national refinement

- countries can be compared at the level of sections and groups
- at the fifth digit and deeper there is no comparability — that is national detail
- the dot in Russian codes sits exactly where the inherited part ends

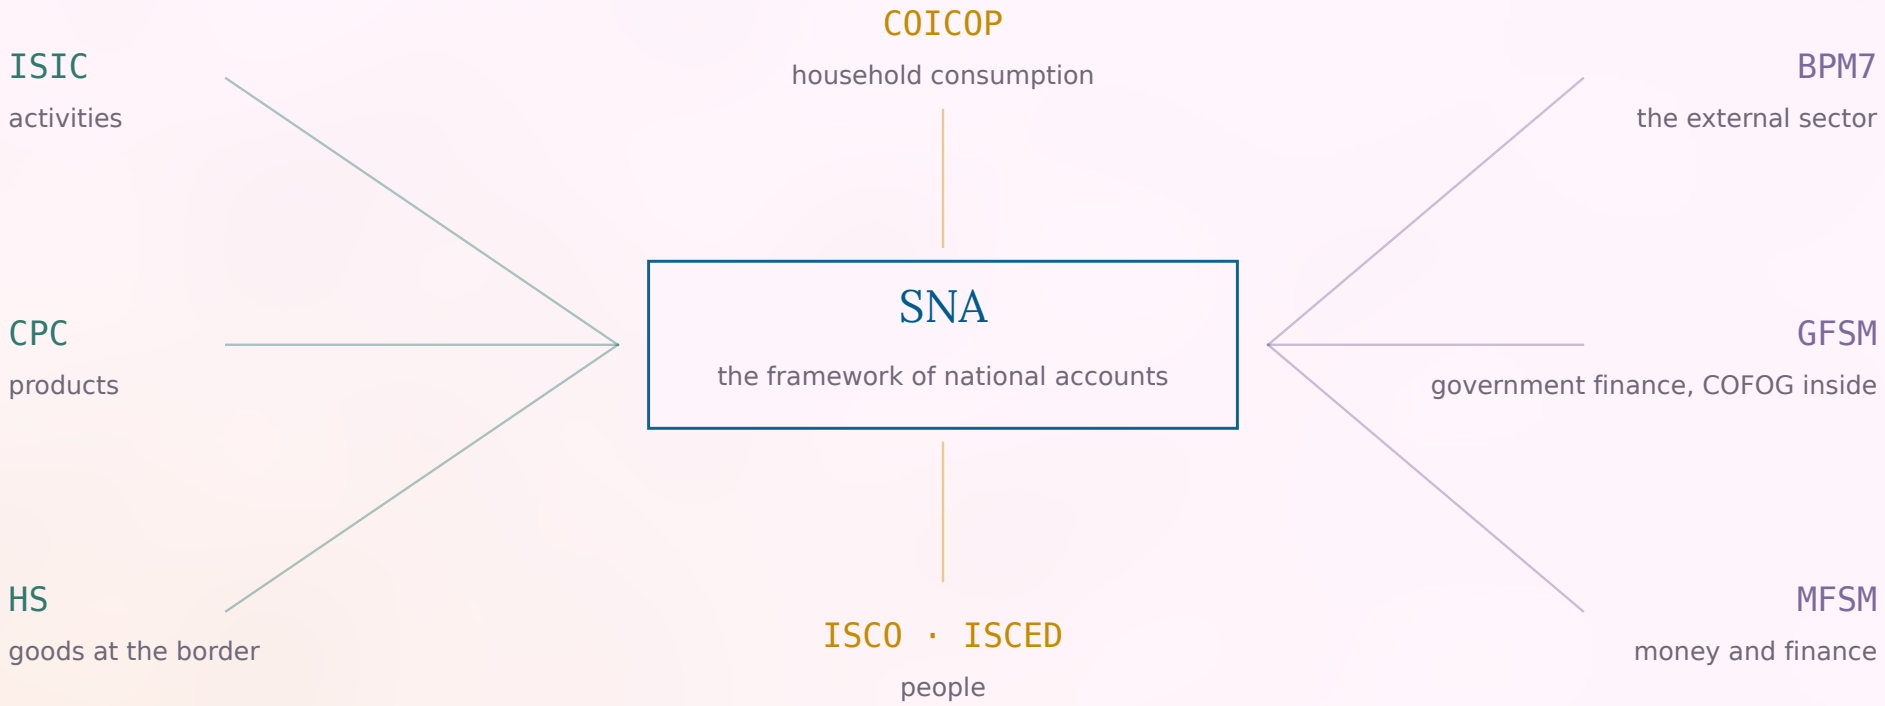

II

Economic classifications

the international standards: the frameworks of accounts and the vocabularies for them

International classifications and the links between them

the SNA sits at the centre: it sets the rules, the others supply the vocabulary

Russia applies the same standards, but through its own classifications — there is a separate section on that.

Where international organisations get their data

the country supplies them itself: membership carries an obligation to report

There is no single treaty “on statistics”. The obligation follows from the organisation's charter: in joining the IMF a country accepts its Articles of Agreement, and Article VIII requires it to provide data for surveillance.

what it is	how it is arranged
dissemination standards	a list of indicators, their frequency and the deadlines for publication
publication calendar	the country announces in advance when each indicator will appear
transmission format	SDMX — a common machine format for series and their descriptions
metadata	a description of the method: coverage, source, departures from the standard

Transmission is continuous, not one-off: each indicator has its own deadline, and missing it is visible — the calendar is public.

The SDDS: a promise to publish, not an obligation to compile

the IMF Special Data Dissemination Standard

- a list of indicators: accounts, budget, money, external sector, population
- for each one — a minimum frequency and a deadline for release
- the calendar is announced in advance, usually a quarter or a year ahead
- metadata are published alongside the data: coverage, method, departures

The standard does not say how to compile an indicator — the SNA, BPM and GFSM do that.
It says what exactly, how often and by what date a country undertakes to publish.

There are two tiers: a basic one and an enhanced one, with stricter requirements on timing and coverage.

Three different things the IMF does with the same data

the country sends a series — three things can happen next, and in the database they look alike

The IMF published it as received

it received the series under the dissemination standard and posted it unchanged — these are the national summary data

The IMF converted it

it took the series in roubles and converted it to dollars at its own rate, then aligned the frequency and classification

The IMF added its own estimate

it added its own seasonal adjustment, filled in uncovered periods and estimated the current year, which the country has not yet published

Hence the discrepancy: annual Russian GDP from Rosstat and from the IMF review differ both in dollars and in growth rate — although the source data are the same.

That is why a table always names not only the country and the year but the source: national or international.

The SNA is a framework, not a classification

it defines what counts as production, income and an asset

- the production boundary: what belongs in GDP and what does not
- institutional sectors: who is who in the economy
- valuation rules: market prices, the moment of recognition, accrual
- the sequence of accounts: from output to the financial account

Russia applies the 2008 SNA as it stands — it takes the definitions, boundaries and sequence of accounts from the standard and adapts only the data sources and the depth of the tables.

Classifications are its vocabulary: without the framework they do not add up to an economy.

Versions of the SNA and what each one added

the basic construction has not changed since 1953, only the coverage has

version	what appeared
1953	the first agreed accounts: production, income, expenditure
1968	input-output tables and accounts for financial transactions
1993	the full sequence of accounts, balance sheets, the production boundary
2008	financial instruments, intellectual property as an asset
2025	data as an asset, digital platforms, global groups, the informal sector

No revision has cancelled the previous one: series are recalculated backwards, so comparability survives — but only after that recalculation.

2008 SNA 2025 SNA: what changes in substance

the basic construction is kept, the coverage is widened

area	what is added
the digital economy	data as an asset, platforms, free digital services
globalisation	multinational groups, processing abroad
the informal sector	explicit treatment in the standard tables
wellbeing and sustainability	a chapter of its own and supplementary accounts
finance	new instruments, a refined sectorisation

BPM7 was adopted at the same time and aligned with the 2025 SNA: external transactions and domestic accounts no longer differ in their definitions.

The balance of payments: BPM6 BPM7

in Russia it is compiled by the Bank of Russia

- the current account, the capital account, the financial account
- residence, not citizenship and not the jurisdiction of registration
- EBOPS gives the detail of services; FATS covers the activity of foreign affiliates
- the international investment position is the stock behind the flows of the balance of payments

Russia applies BPM6 with no national departures; the move to BPM7 lies ahead.
BPM7 refines digital services, crypto assets and transactions inside multinational groups.

Versions of the balance of payments manual

each one is closer to the SNA than the last

version	what appeared
1948, BPM1	the first agreed form of reporting to the IMF
1977, BPM4	the split between the current account and the capital account
1993, BPM5	alignment with the 1993 SNA, residence as the governing principle
2009, BPM6	the international investment position, detail of services
2025, BPM7	digital services, crypto assets, transactions inside global groups

BPM7 was adopted together with the 2025 SNA and aligned with it: external transactions and domestic accounts no longer differ in their definitions.

The IMF's GFS: not only expenditure

government finance statistics describe the whole sector, not just the budget

GFS block	what it covers	where it is used
revenue	taxes, contributions, property income	the structure of the revenue base
expenditure	by economic type of transaction and by function (COFOG)	fiscal policy
balance sheet	non-financial and financial assets	the net worth of the sector
debt	liabilities by instrument and maturity	debt sustainability
financing	how the deficit is covered	the link to monetary statistics

GFSM 2014 is aligned with the SNA: the general government sector in fiscal statistics and in the national accounts must agree. The functional line is COFOG, which comes on the next slide.

COFOG

Versions of GFS and COFOG

fiscal statistics moved from cash to accrual

version	what appeared
GFSM 1986	cash accounting: what was actually paid and received
GFSM 2001	the move to accrual and to a balance sheet, alignment with the SNA
GFSM 2014	alignment with the 2008 SNA, a refined sector boundary
COFOG 1980	the first classification of the functions of government
COFOG 1999	the version in force: ten divisions
revision	under way now: climate, digital government, new functions

COFOG: what the state spends on

ten divisions by purpose, regardless of which ministry pays

01 general public services

02 defence

03 public order and safety

04 economic affairs

05 environmental protection

06 housing and community amenities

07 health

08 recreation, culture and religion

09 education

10 social protection

The point is that “spending on education” should mean the same thing in countries with differently organised governments. A revision of COFOG is under way.

Refinery: the fuel subsidy sits in division 04.3, fuel and energy

ISIC: a classification of what the producer does

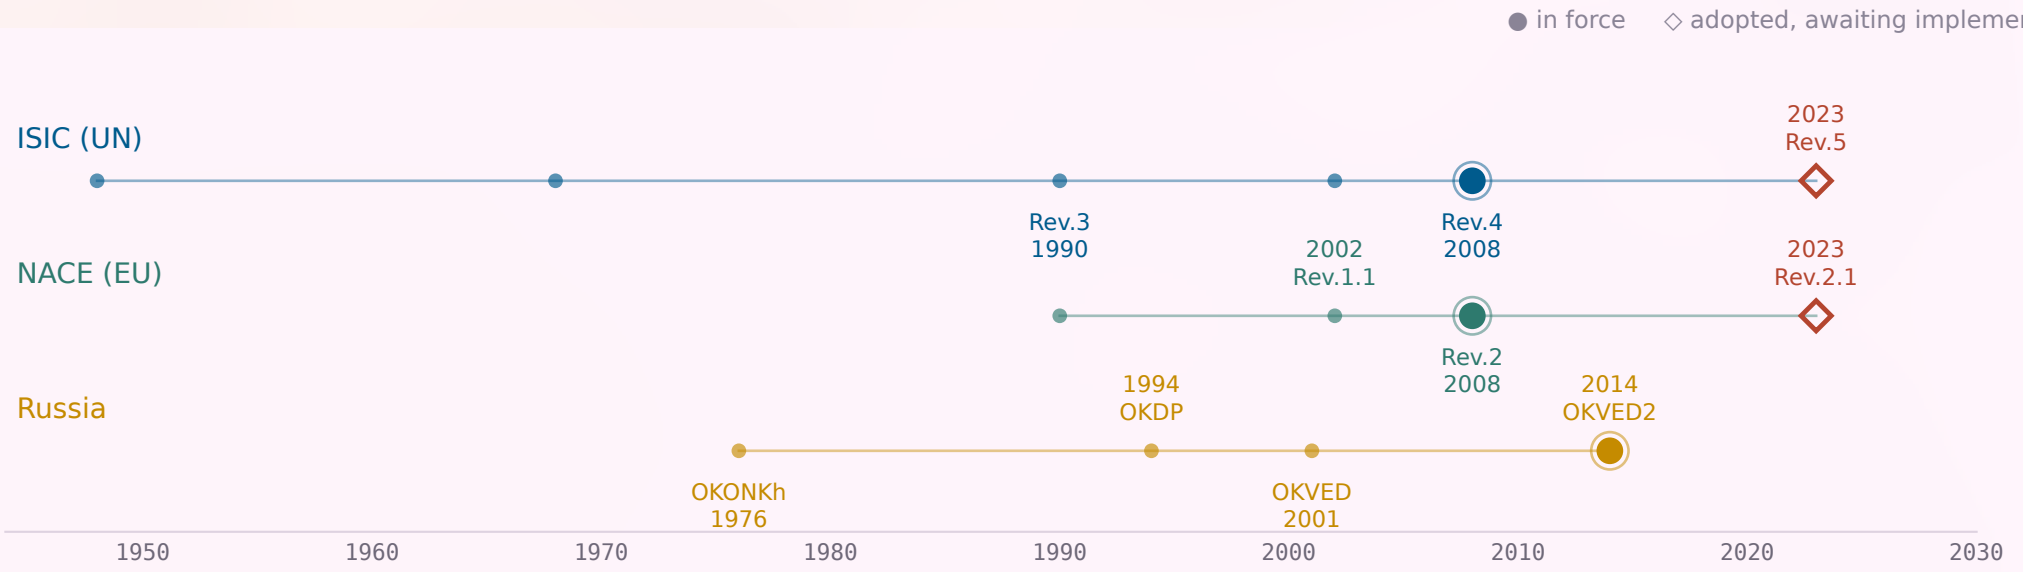

the basic question is what process runs at the site, not which company owns it

- the unit of classification is the establishment: a site with a single process
- the principal activity is the one with the largest value added
- four levels: a section letter, then two, three and four digits
- the whole industry structure of GDP and productivity rests on it

A company with several plants gets several codes — one per establishment.
“The company's code” exists only in administrative registers.

OKVED inherits from NACE, NACE from ISIC

three branches of one family and the dates when the next generation is due

> Dates: ISIC Rev.5 was adopted in 2023, national adaptations fall in 2025–2026, and statistical use starts in 2027. In the EU, NACE Rev.2.1 comes in by stages.

The Russian branch is covered in its own section, with the dates of the transition.

What each version of ISIC and NACE brought

the classification catches up with the economy a generation late

version	what was added or changed
ISIC Rev.3, 1990	services and financial intermediation set apart
ISIC Rev.4, 2008	information and communication as a separate section, professional services
NACE Rev.2, 2008	the European version of Rev.4, binding on EU countries
ISIC Rev.5, 2023	digital platforms, intermediaries, processing on a toll basis
NACE Rev.2.1, 2023	the European version of Rev.5, rolled out from 2025

The next Russian version is called OKVED 3 and is built on NACE Rev.2.1 — the dates and the substance of the transition are in the Russia section.

ISIC Rev.5: where the industries move to

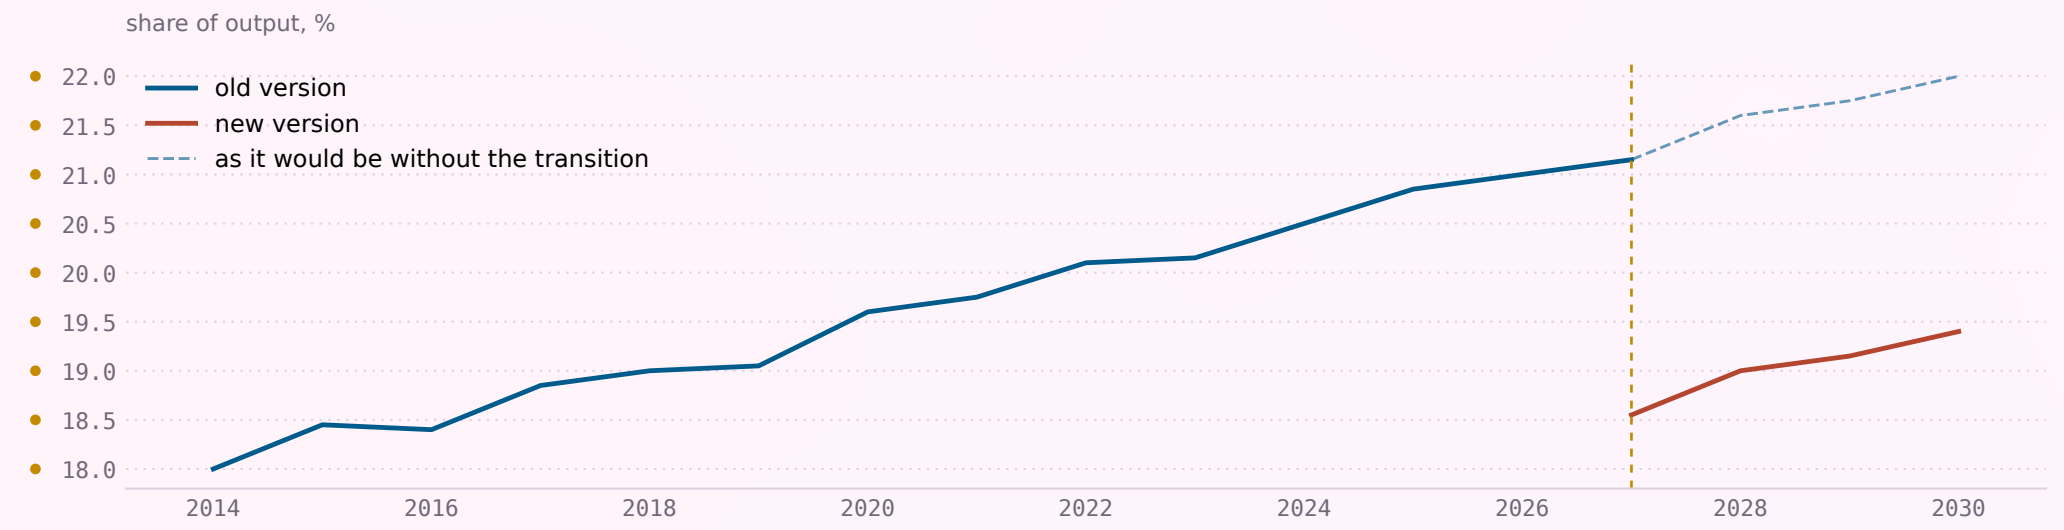

the coding stays, but the content of the groups changes

- information and communication are split: telecoms apart from IT and media
- new groups for digital platforms and intermediation services
- toll processing is assigned to where the decision is taken
- the detail has grown — more groups at the same code length

A practical consequence: the share of “manufacturing” in GDP will change without a single change in the economy. That is a break in the series.

A change of version moves an industry, it does not change the economy

the series breaks where nothing actually happened

So with long series one first finds where the version boundary runs, and only then computes growth.

CPC: a classification of what came out at the end

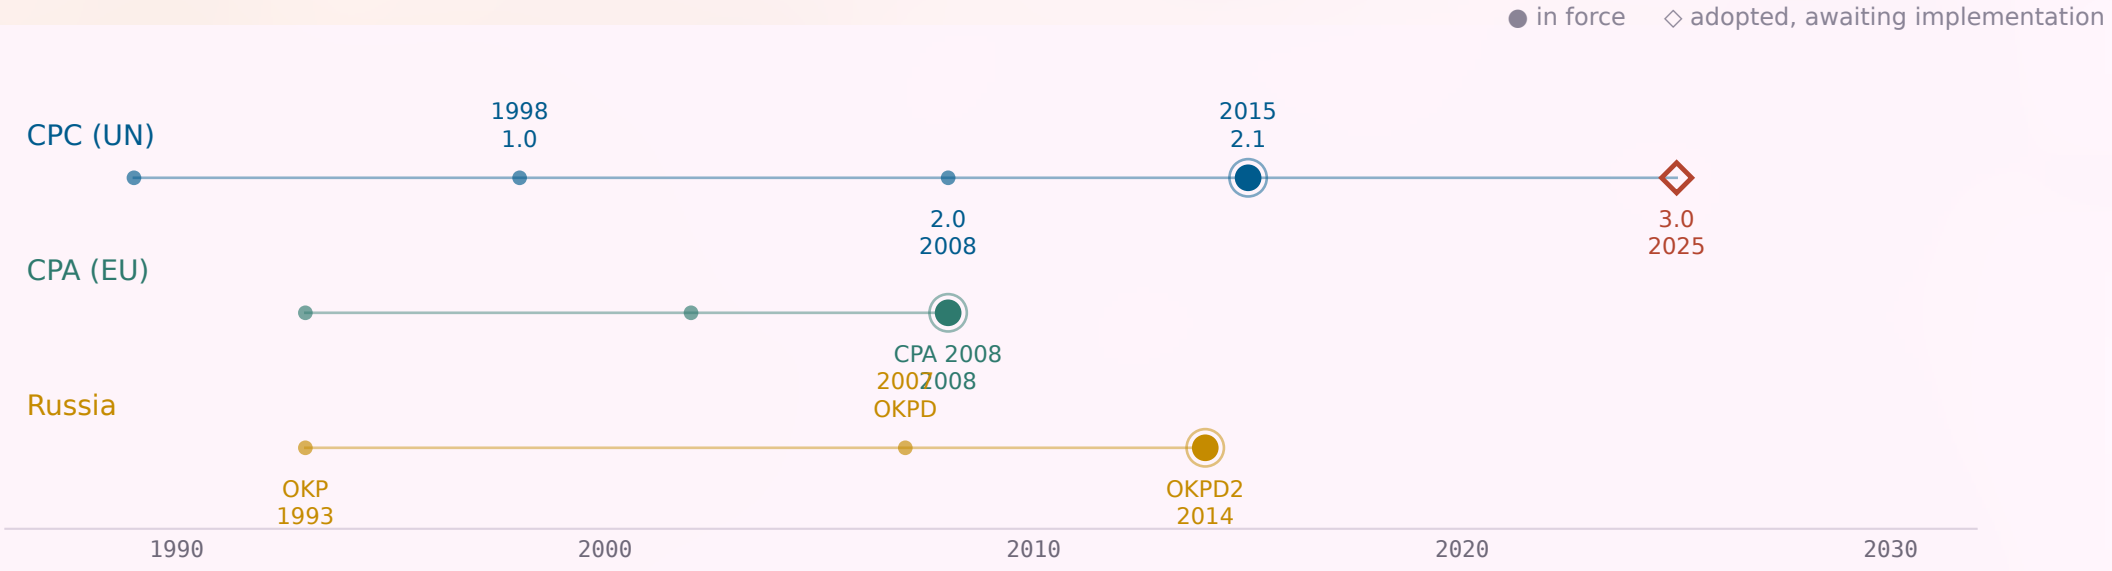

the same product can be made by different activities

- it covers goods and services in a single scheme
- grouping by the physical properties and the purpose of the product
- it bridges production, trade and consumption
- the European CPA is tied to NACE: a product code starts with the activity code

The link to activities is not accidental but built in: CPA was designed so that supply-and-use tables balance without manual correspondence tables.

The lineage of products: CPC CPA OKPD2

OKPD2 is built directly on OKVED2: a product code starts with the activity code

> CPC 3.0 was endorsed in 2025 and aligned with ISIC Rev.5 and the 2025 SNA. OKPD2 still rests on CPA 2008 — two generations apart.

The link to OKVED2 is direct: 19.20 is the activity, 19.20.21 its product, so industry and product tables reconcile without extra work.

THE LINK

One litre of petrol, four questions and four codes

the shared part of the code shows where the classifications join up and where they do not

OKVED2

19.20

who produced it

OKPD2

19.20 .21

what was produced

TN VED

2710

what was exported

COICOP

07.2.2

what it was spent on

19.20 is the shared part: OKPD2 is built directly on OKVED2

TN VED and COICOP share no part: they follow a different logic — the good at the border and the purpose of the purchase — so correspondence tables are needed between them.

That is why output, exports and consumption never reconcile exactly without adjustments.

HS: the fastest-moving classification of them all

the Harmonized Commodity Description and Coding System

Revised every five years: trade changes faster than production.

- HS is maintained by the World Customs Organization: a customs standard, not a statistical one
- six digits are binding on all parties, beyond that countries and unions subdivide on their own
- revised every five years, with all countries switching at the same time
- tariff rates hang on the code, so a revision touches regulation as well

The key difference from product classifications: HS describes the good as it crosses the border. The same petrol carries different codes as a product and as a traded good.

Refinery: 2710 — oil and petroleum products on export

Correspondence tables between the families exist, but they are approximate

the classifications answer different questions, so the match is never complete

pair	table exists	where it is inexact
CPC and HS	official	HS is the good at the border, CPC the product of production
COICOP and CPC	official	COICOP goes by the purpose of the purchase, CPC by properties
ISIC and CPC	built in	one product is made by several industries
NACE and the industries of GDP	they are the same thing	but counted by establishments, not by legal entities

The same litre of petrol

CPC
a product of oil refining

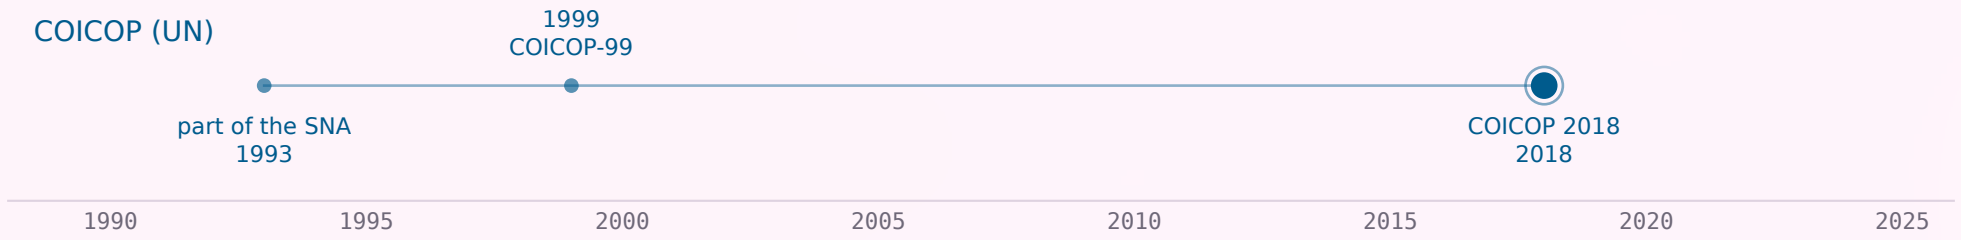

HS
a good that crossed the border

COICOP
a household's transport expense

“Industry” in the accounts and “industry” in the company register are different things too.

COICOP: what households spend on

the basis of the consumer basket, and hence of the consumer price index

- twelve divisions, from food to miscellaneous goods and services
- what is classified is the purpose of the purchase, not the seller or the producer
- in Russia the Rosstat structure of expenditure is comparable but not identical

Refinery: 07.2.2 fuel for personal transport — this is how petrol enters the CPI

Harmonised inflation: how the EU solved the same problem

a common COICOP proved not to be enough; a common method was needed

- common rules of coverage and compilation, not just a common classification
- expenditure on the country's territory is counted, including purchases by visitors
- owner-occupied housing stays outside the headline index and is tracked separately
- weights are updated annually on a common schedule

The result: EU indices are directly comparable with one another, while national indices continue to exist and differ from the harmonised one.

The general lesson: a classification alone is not enough for comparability — a common method is needed.

One COICOP, yet national CPIs are not directly comparable

the classification is shared, the content is national

- the weights of the divisions come from the national structure of expenditure
- housing is treated differently: rent, imputed rent, or outside the scope altogether
- the set of representative items inside the groups differs by country
- the frequency of weight revisions differs

Inflation levels can be compared across countries, contributions with reservations, and individual groups only if one knows exactly what went into them.

III

People, units, territories

the things without which no table can be assembled

Occupations, status, education

the three classifications that labour market statistics rest on

what is coded	international standard	in Russia	who maintains it
occupation	ISCO-08	OKZ	Ministry of Labour
status in employment	ICSE-18	used in surveys	Rosstat
education	ISCED 2011	OKSO	Ministry of Education and Scie

These codes feed the estimate of labour market slack and Okun's law, which the deck on trend extraction covered.

Refinery: 3134 petroleum refining plant operators — a group of their own in ISCO

SNA sectors and their Russian counterparts

sectorisation decides which account a transaction lands in

SNA sectors

non-financial corporations

financial corporations

general government

households

non-profit institutions

the rest of the world

Russian counterparts

OKOPF	legal form
OKFS	form of ownership
OKOGU	governing body
OKPO	code in the statistical register

A sector is not the same as a form of ownership: a state-owned company selling at market prices belongs to non-financial corporations, not to general government.

Territory, countries, currencies, units of measurement

the dullest part — and the commonest cause of errors in data

classification	what it codes	based on
OKTMO	municipalities, the main one in the budget	national
OKATO	administrative division, being phased out	national
OKSM	countries of the world	ISO 3166
OKV	currencies	ISO 4217
OKEI	units of measurement	UNECE Recommendation 20

OKTMO and OKATO coexist: the budget moved to OKTMO while some statistical series stayed on OKATO — hence the discrepancies when regions are added up.
Half the discrepancies in data are tonnes versus thousands of tonnes.

Refinery: tonnes under OKEI, the site's OKTMO, the OKSM of the export destination

IV

Russia:
its own codes and registers

what is inherited, what is domestic, and what changes in the next few years

The Russian branch starts from a different ontology

not a different numbering but a different idea of what creates value

USSR, before 1993

The Material Product System

only material production was counted

services largely did not count as creating value

OKONKh classified “branches of the national economy”

the unit of observation was an enterprise within a branch

Russia, from 1993

The System of National Accounts

all production is counted, services included

the production boundary is stated explicitly

OKVED classifies activities

the unit of observation is the institutional unit

The transition began in 1993. The breaks in long Russian series come from there, not from changing editions of OKVED.

Russian classifications and what they inherit from

nearly every one has an international ancestor, but subdivides further and lives its own life

classification	international basis	who maintains it	what lies ahead
OKVED2	NACE Rev.2 ← ISIC Rev.4	Ministry of Economic Development	OKVED 3 from 2029
OKPD2	CPA 2008 ← CPC	Ministry of Economic Development	OKPD 3 from 2029
TN VED EAEU	HS 2022	the Eurasian Commission, applied by customs	following HS 2028
KBK and KOSGU	GFSM, COFOG in part	Ministry of Finance	—
OKZ	ISCO-08	Ministry of Labour	—
OKSO	ISCED 2011	Ministry of Education and Science	—
OKTMO, OKATO	domestic	Rosstat and Rosstandart	—
OKOPF, OKFS, OKPO	domestic	Rosstat and Rosstandart	—

Two rows have no international basis and are purely domestic: territorial division and forms of ownership. Everything else is inherited.

ISIC NACE OKVED: what is in force now

what is classified is the activity, not the enterprise

level	version in force	next version	who maintains it
world, ISIC	Rev.4 (2008)	Rev.5, adopted in 2023	UN Statistical Commission
EU, NACE	Rev.2 (2008)	Rev.2.1, being introduced	Eurostat
Russia, OKVED2	OK 029-2014	no decision yet	Ministry of Economic Development

Countries adapt their national classifications in 2025–2026 and switch from 2027.
In the EU both versions run side by side for a while:
Slovakia, for instance, publishes national results in the old version until 2028.

Refinery: 19.20 manufacture of petroleum products — section C, manufacturing

A RUSSIAN FEATURE

OKVED lives two lives

a statistical one and an administrative one, and they need not coincide

Statistical

assigned by Rosstat from reported data

the basis of industry series and the national accounts

the unit is an establishment or an institutional unit

Administrative

the company picks the code itself at registration

used for taxes, licences and support measures

the unit is a legal entity

Hence the systematic gap between the tax and the statistical picture of industries.
When reconciling data this is the first thing to check.

OKVED 3 and OKPD 3: the switch is set for 2029

the last update was more than ten years ago

2026	ISIC Rev.5, NACE Rev.2.1, CPC 3.0 and CPA translated; a draft OKVED 3 prepared
2027	a draft OKPD 3, forward and backward correspondence tables, a list of composite groupings
2028	the classifications are approved, the legal acts adopted, a one-year transition period begins
2029	business and the state move to the new classifications

The basis is NACE Rev.2.1, the European adaptation of ISIC Rev.5: international comparability is kept and Russian specifics move to the deeper digits.

The previous switch took ten years, this one is planned for three. The new groups are digital platforms, creative industries and technology companies.

CPC CPA OKPD2

a product is the result of an activity, not an object of a border transaction

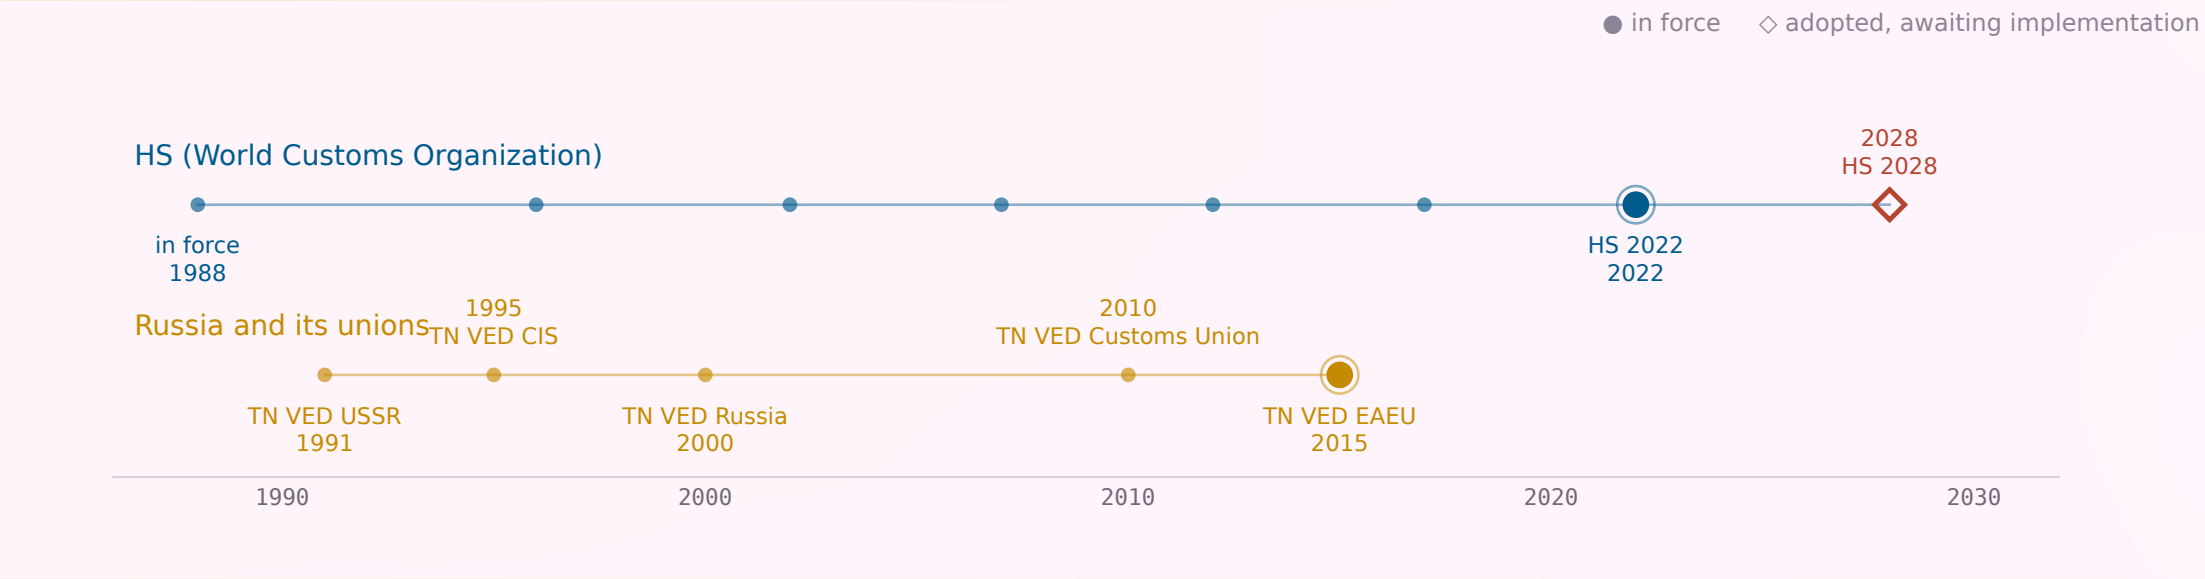

level	version in force	next version	who maintains it
world, CPC	Ver.2.1 (2015)	Ver.3.0, endorsed in 2025	UN Statistical Commission
EU, CPA	CPA 2008	updated in step with NACE	Eurostat
Russia, OKPD2	OK 034-2014	OKPD 3 from 2029	Ministry of Economic Developmer

OKPD2 is built on CPA 2008 — two generations away from CPC 3.0.
For comparison with the world nomenclature that is already a noticeable distance.

Refinery: 19.20.21 motor petrol — the product the plant makes

TN VED inherits from the Harmonized System

and changes its regional home as integration proceeds

> The six HS digits are international and binding on all parties; digits seven to ten are added by the EAEU itself.

in force

Exports by customs and in the balance of payments do not match

one indicator, two sources, and both are right

Customs statistics

counts the crossing of the border

the source is customs declarations

classified by TN VED

blind to transactions without a declaration

Balance of payments

counts the change of ownership

the source is reporting by banks and companies

classified under BPM

adds what the declarations do not contain

What makes up the difference: bunkers and stores sold to ships abroad; goods bought and resold without entering the country; an adjustment for unrecorded shipments.

So when reconciling foreign trade one always names the source: customs or the central bank.

The Rosstat consumer basket and COICOP

the classification is international, the content and selection rules are domestic

How Rosstat compiles it

a set of representative goods and services, revised annually

weights come from the household budget survey

prices are collected in selected cities and outlets

owner-occupied housing is not in the index

How it differs from COICOP

COICOP sets only the grouping by purpose of expenditure

below the top divisions the structure is already national

the country chooses the content of groups and the representative items

divisions are comparable, individual items are not

So the Russian CPI and the EU harmonised index follow the same logic of groups but not the same basket — levels by item cannot be compared.

Refinery: petrol enters the basket as fuel for personal transport

The Russian budget classification and COFOG

one transaction is coded three times: by economic type, by function, by ministry

layer	the question it answers	in Russia
economic	what kind of transaction	KOSGU
functional	for what purpose	budget divisions → COFOG
departmental	who administers the funds	KVR and chapters

Example: a school buys fuel for its bus

economic layer	KOSGU 343 — increase in the value of fuels and lubricants
functional layer	division 07 “Education” → COFOG 09
departmental layer	KVR 244 — purchase of goods for the institution's needs

One transaction, three answers: what kind of spending, for what purpose, and who pays.

Where the codes live: registers, not reference books

the classification sets the language, the register stores what was assigned to each object

register	who maintains it	what it holds
EGRUL and EGRIP	Federal Tax Service	legal entities and sole traders, their OKVED codes
SME register	Federal Tax Service	small and medium business status
Statistical register	Rosstat	OKPO, actual activities
Customs statistics	Federal Customs Service	declarations carrying TN VED codes
Financial market directories	Bank of Russia	credit institutions, issuers
EGRN	Rosreestr	real estate objects and title

From 2026 Rosstat computes the actual OKVED code from reported data and passes it to the tax registers: one in five reporting organisations saw its main code change.

The tax reform: twenty bases merged into one

the bill was introduced in autumn 2026; if passed, it applies from 2027

Before the reform

wages — their own schedule

dividends — their own rate

bank interest — its own

securities — their own

property sales — their own

and so on, two dozen bases

After the reform

a resident's twenty bases are added together

a single progression of 13–22%

deductions apply within the combined base

non-residents have their own set of 17 bases

banks withhold tax on interest immediately

the tax arrives in the year the income accrues

The bases accumulated one at a time: each new kind of income got its own line in the code with its own rate. The reform does not abolish them, it adds them up to set the rate.

For statistics the second point matters: the moment of recognition shifts, and the series of personal income tax receipts for 2027 will not be comparable with the past.

What hardly exists elsewhere

administrative features one has to allow for in calculations

feature	what it is	what it means for the data
OKVED in the register	the company picks the code itself	the tax and statistical pictures of industries diverge
OKATO and OKTMO	two territorial systems at once	the correspondence is incomplete
OKFS	forms of ownership as a separate classification	a legacy of planned accounting
KOSGU	a code for the kind of spending on top of the purpose and ministry codes	it does not map one-to-one onto COFOG
OKEI	units of measurement as a separate standard	elsewhere the UN recommendation is used

The first row costs the most in practice: a statistical unit and a legal entity are different objects.

IV

Statistics and company accounts

why profit under IFRS and the profit of an economy are different quantities

Why the figures in accounts and in statistics do not agree

it is not about data quality: different things are being measured

difference	in the accounts	in the national accounts	example
unit	a legal entity or a group	a resident unit	a plant and its trading arm — one company or two
valuation	historical cost	market prices	a 1980 building on the balance sheet and in the accounts
boundary	goodwill and development costs	a boundary of its own	a purchased brand is in the accounts, not in the national accounts
consolidation	the whole group	by residence	a foreign plant belongs to the group but not to GDP

None of the four differences goes away by recalculation: these are different definitions of the subject, not different ways of measuring the same thing.

EXAMPLE

Three lines from our refinery's accounts and what statistics do with them

the same event lands in different indicators

line	in the accounts	in the SNA
profit	net profit under IFRS, after tax	gross operating surplus, before interest
depreciation	by useful life	at replacement cost
revaluation of inventories	a rise in the value of stocks adds to profit	holding gains are excluded from output

The third line is the treacherous one: when oil prices jump the company's profit rises, while the industry's output in constant prices may not move at all.

Bridging tables: they exist for government, not for business

the asymmetry is understandable, but worth knowing about

The government sector

— GFSM 2014, appendix 6 — a line-by-line comparison with the international public sector accounting standards (IPSAS)

— the board behind those standards (IPSASB) has taken statistical requirements into account since 2014

— a joint alignment dashboard for the two systems is maintained and is being updated

— in the EU the same idea is pursued through the EPSAS project

The corporate sector

— no agreed table between the SNA and IFRS, or the SNA and US GAAP, exists

— the closest thing is the UN handbook Links between Business Accounting and National Accounting, 2000

— it was written for the 1993 SNA, before IFRS was adopted widely

— each statistical office builds the bridge itself, around its national accounts standards

— the reason: government accounts are themselves an instrument of policy, while corporate ones serve the investor

How company accounts can still be reconciled with industry statistics

what can be done, and what is pointless

- ✓ compare dynamics: the growth of industry revenue against output in the statistics
- ✓ compare structure: the shares of segments within an industry
- ✓ use the accounts as a leading indicator — they come out earlier
- ✕ compare levels: company profit and the profit of an economy are different quantities
- ✕ add up company revenue to get the output of an industry
- ✕ carry an industry assignment from GICS over to OKVED

US GAAP is no different here: a different level of detail, the same nature of divergence from statistics.

V

Where this breaks in practice

changing versions, correspondence tables and a living economy

A correspondence table is rarely one-to-one

and exactly where it is complex, the recalculation becomes an estimate

1 : 1	the group moved as a whole	the recalculation is exact
1 : n	the group was split	weights from a year of parallel coding are needed
n : 1	groups were merged	exact in the reverse direction
n : m	the boundaries were redrawn	only an approximate recalculation is possible

The weights come from a year when both versions were coded in parallel. If there was no such year, the recalculation rests on expert judgement — and that belongs in a footnote.

Double coding: a year or two in both versions

expensive, but the only way to get an unbroken series

- the EU moved to NACE Rev.2.1 in stages: registers first, statistics later
- some EU countries switched in 2025, the rest are following
- Slovakia publishes national results in the old version until 2028
- during the transition, correspondence tables between codes are published

For an analyst this means that in 2026–2028 countries will be on different versions, and comparing industry structures over that period needs a caveat.

A classification always lags behind the economy

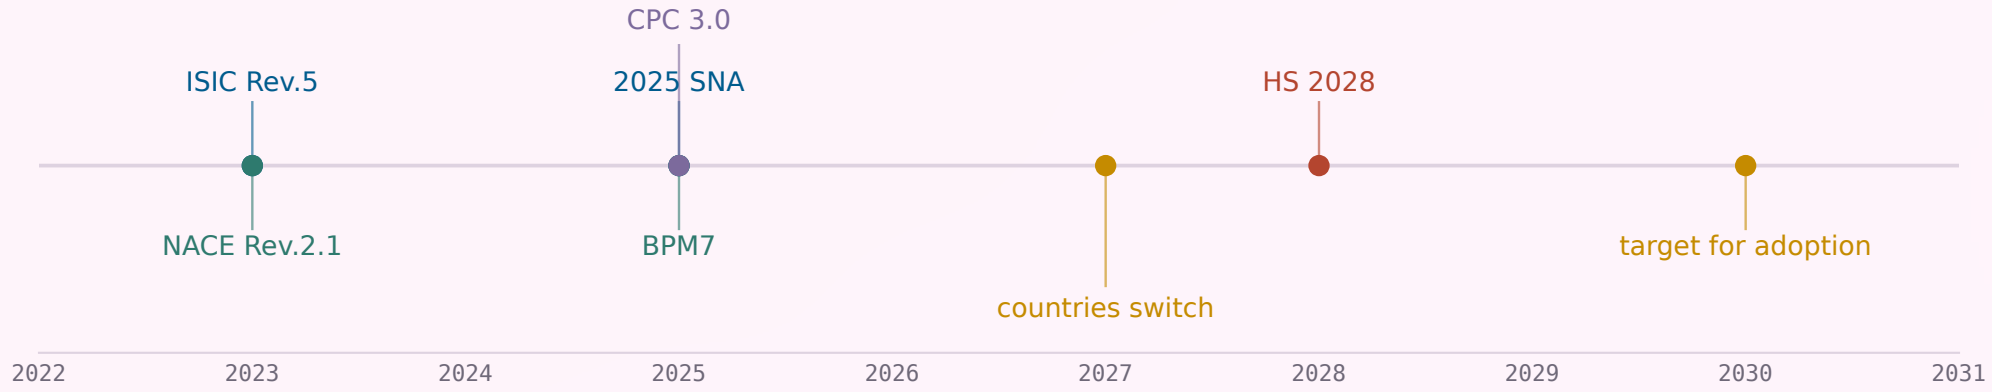

and that is not a defect but a property of any standard

- hybrid production: a plant sells both a product and the service of maintaining it
- digital platforms: intermediary, seller or infrastructure
- services with no place of supply: where is it produced if provider and client are in different countries
- toll processing: whose output is it

Each revision closes the cases that have piled up and opens new ones.
That is why versions change roughly every fifteen years, not once and for all.

A change of generation in the standards is under way right now

there has been no such coincidence of dates since the early nineties

For Russia: adopting the 2025 SNA is a stated priority of the strategy to 2030, and the switch to OKVED 3 and OKPD 3 is set for 2029.

Who carries out the transposition in Russia

the central table of the deck: whom to approach about each code

area	international basis	responsible body
OKVED2, OKPD2	NACE Rev.2, CPA 2008	Ministry of Economic Development
national accounts, CPI	SNA, COICOP	Rosstat
balance of payments, monetary statistics	BPM, MFSM	Bank of Russia
budget classification	GFSM, COFOG	Ministry of Finance
TN VED	HS	the Eurasian Commission, applied by customs
OKZ, OKSO	ISCO, ISCED	Ministry of Labour, Ministry of Education and Science
maintenance of the all-Russian classifications	—	Rosstandart

There is no single authority: each family has its own owner, and changes go there, not “to statistics in general”.

RUNNING EXAMPLE

The object's passport: one plant in full

everything collected along the way

activity	OKVED2 ← NACE ← ISIC	19.20
product	OKPD2 ← CPA ← CPC	19.20.21
exports	TN VED ← HS	2710
energy product	SIEC	motor petrol
equipment imports	HS + BEC	a capital good
sale to households	COICOP	07.2.2
subsidy	COFOG + KOSGU	04.3
taxes	GFSM	general government revenue
foreign currency proceeds, debt	BPM7	BoP accounts
staff	OKZ ← ISCO	3134
legal form and ownership	OKOPF, OKFS	a public joint-stock company
location, units, country	OKTMO, OKEI, OKSM	tonnes
emissions and abatement	SEEA, CEPA	emission accounts
for the investor	GICS, ISIN, LEI	the Energy sector
financial reporting	IFRS, RSBU	two profits

Fifteen lines about one plant, and not one of them is “the company's code”.

An analyst's checklist

01 state the version of the classification and the year, not just its name

02 when comparing countries, check how many digits the harmonisation covers

03 with long series, find the version boundaries before computing growth rates

04 do not mix the register's OKVED with the statistical industry assignment

05 check the units of measurement as carefully as the codes

06 for markets, do not substitute GICS for industry statistics or the other way round

07 when data diverge, look at the classification first and the method second

Where to look for primary sources

every classification mentioned here is publicly available

resource	what is there
macro-rus.streamlit.app/Sources	an archive of links to primary sources that I maintain
data.imf.org	IMF data: accounts, budget, external sector
unstats.un.org/unsd/classifications	ISIC, CPC, COICOP, COFOG and the tables between them
ec.europa.eu/eurostat/ramon	NACE, CPA, PRODCOM, correspondence tables
wcoomd.org	the Harmonized System
protect.gost.ru	the all-Russian classifications
eec.eaeunion.org	TN VED EAEU

Correspondence tables are published together with the classifications — download them straight away.

continued

What even the 2025 SNA and BPM7 leave unresolved

the new standards cleared the backlog, but not all of it

topic	what remains unresolved
crypto assets	the class is defined, but valuation and the holder's residence remain contested
data as an asset	recognised as an asset, yet there is no common practice for valuing them
artificial intelligence	a model as fixed capital, training as investment — the question is open
free digital services	consumed by everyone, absent from GDP
platform work	employee, contractor or entrepreneur — treated differently across countries
climate and natural capital	the accounts remain satellite ones, outside GDP

A generation from now all of this will be the substance of the next revision — as the digital economy became the substance of the present one.

thank you

Appendix:
glossary of abbreviations

international and Russian, with expansions and explanations

Abbreviations: international, part 1

the abbreviation, how it expands, what it means in practice

SNA	System of National Accounts	the framework of national accounts
BPM	Balance of Payments Manual	the rules of the balance of payments
GFSM	Government Finance Statistics Manual	the rules of fiscal statistics
MFSM	Monetary and Financial Statistics Manual	the rules of monetary statistics
ESA	European System of Accounts	the SNA version used in the EU
ISIC	International Standard Industrial Classification	activities, worldwide
NACE	Nomenclature statistique des Activités économiques	activities, EU
CPC	Central Product Classification	products, worldwide
CPA	Classification of Products by Activity	products, EU
HS	Harmonized System	goods at customs
SITC	Standard International Trade Classification	trade, long series

continued

Abbreviations: international, part 2

BEC	Broad Economic Categories	goods by end use
PRODCOM	Production Communautaire	industrial output, EU
SIEC	Standard International Energy Classification	energy products
COICOP	Classification of Individual Consumption by Purpose	household consumption
COFOG	Classification of Functions of Government	functions of government
ISCO	International Standard Classification of Occupations	occupations
ISCED	International Standard Classification of Education	education
SEEA	System of Environmental-Economic Accounting	natural capital
IPSAS	International Public Sector Accounting Standards	public sector accounting
SDMX	Statistical Data and Metadata eXchange	a data exchange format
SDDS	Special Data Dissemination Standard	what a country publishes and when

Russian ones

Abbreviations: Russian, part 1

the abbreviation, how it expands, what it corresponds to

OKVED	classification of economic activities	inherits from NACE and ISIC
OKPD	classification of products by activity	inherits from CPA and CPC
OKONKh	classification of branches of the national economy	until 2003, the Material Product System
TN VED	commodity nomenclature for foreign trade	built on top of HS
OKZ	classification of occupations	inherits from ISCO
OKSO	classification of fields of education	inherits from ISCED
OKTMO	classification of municipal territories	the one used in the budget
OKATO	classification of administrative-territorial division	being replaced by OKTMO
OKSM	classification of countries	based on ISO 3166
OKV	classification of currencies	based on ISO 4217
OKEI	classification of units of measurement	based on the UN recommendation

thank you

Abbreviations: Russian, part 2

OKOPF	classification of legal forms	joint-stock companies, limited companies and the rest
OKFS	classification of forms of ownership	state, private and so on
OKOGU	classification of government bodies	which ministry a body belongs to
OKPO	an enterprise's code in the statistical register	maintained by Rosstat
KBK	budget classification codes	how a budget code is built
KOSGU	classification of general government operations	what kind of spending it is
KVR	budget expenditure type code	what exactly the money goes on
BNKh	the Material Product System	the Soviet accounting system before the SNA
RSBU	Russian accounting standards	company financial reporting
EGRUL	the unified state register of legal entities	maintained by the tax service
ENS	the unified tax account	settlements with the budget as a single balance

thank you
